

ITE 298 - Modules 12 & 13 Activity

Name: Resty S Aldave

System: Managing Sentry (Android POS app + Web Admin Portal + local database)

1. Know Your Audience

Chosen audience: Technical audience. My audience is our client and also the panelists of our project, who know some technical words.

What they need to know:

- The problem of the store, which is the paper receipts, the errors in manual writing, and the slow checkout during peak hours.
- How the system works. The staff uses the Android app to make sales and the admin uses the website to manage the system.
- The technical side, like the local database in the phone, the sync to the server, and the roles of each user.
- How the system keeps the data safe and correct even when there is no internet.
- What the system can and cannot do, so they know the scope and limitations.

2. Explain Your System

Managing Sentry is a Point of Sale and inventory system that we made for Alekos' Corner General Merchandise. It has two connected parts. The staff uses an Android app made in Java to process sales fast, and the admin uses a web portal in the browser to see sales reports and manage products and prices. The website is for the admin because the app is limited on purpose and only has what the staff needs. The app saves all data in a local database in the phone, so it can still work offline and then sync to the server when the internet comes back. The stock updates by itself after every sale and the system gives low stock alerts, so the owner can see accurate records and stop using paper receipts.

3. Plan Your Live Demonstration

Step	What I will demonstrate
1. Introduction	I will start by explaining the problem of Alekos' Corner, like the lost paper receipts, the crossed out text, and the slow checkout during late night. Then I will show the Android app for the staff and the web portal for the admin so they know what they will see.
2. Feature Execution	I will log in on the Android app as a staff and make a sale. I will pick the items, show the total, put the cash amount, and show that the system computes the change. Then I will log in on the website as the admin to show the product prices and stock settings.
3. Data Flow Validation	After the sale, I will show that the stock of the sold items goes down by itself in the inventory. Then I will open the web portal and show that the same sale is in the sales report and the low stock alert shows up.
4. Conclusion	I will recap how the system solves the paper receipt problem, the slow checkout, and the missing reports. Then I will say what we can add next and ask the panelists for their feedback.

4. Show Evidence

Feature: Offline mode and data sync

I chose this feature because offline is the most important requirement of our client. To prove it works, I will use a real phone because the offline feature is only for the phone. I will use a realistic sale from the store, like 2 pieces of Lucky Me Pancit Canton and 1 bottle of 1.5L soft drink (*This may also be change during our demo*), with 200 pesos as the cash tendered.

Here is what I will do:

- First, I will show the top right of the app where the green pulse is. This means the app is online.
- Then I will turn off the network of my phone and show that the green pulse changes to red.
- Next, I will make the sale using the items above and complete the transaction.
- After that, I will go to the history. It will show that the transaction is saved but with a status of Pending.
- Then I will turn on the network and let the app sync the data. After I reload the history, the Pending status will change to Completed and the pulse at the top right will become green again.
- To prove it more, I will open the web portal and show that the same sale is now in the report and the stock is also updated.

5. Reflection

It is important for an IT professional to know how to explain and demonstrate a system because building it is only half of the job. If the client and the users do not understand how it works, they will not trust it and they will not use it. A good demo shows proof that the system really works and it helps us find mistakes before the real users do. It also helps us get clear feedback from the client and the panelists. So I think a good IT professional must build well and also explain well.

6. Peer Feedback (SBI)

Situation: During the Evidence part of my presentation plan,

Behavior: my classmate said that I explained the offline feature step by step and showed the Pending to Completed change, but I did not plan to show what happens if the sync fails or if the internet is very slow,

Impact: which makes it hard for the panelists to see if the system can really protect the data when the connection is not stable.
